# Individual-Population-Species Continuum

"The stream of heredity makes phylogeny" G. G. Simpson, 1945

"Family tree"

"Phylogenetic tree"

Fine scale  
(microevolutionary)

Broad scale  
(macroevolutionary)

# Individual-Population-Species Continuum

---

- DNA sequence analysis: targets taxonomic or phylogeographic (i.e., **Species**) end of the spectrum.

[Broad-brush]

- Microsatellite DNA and allozyme analyses: targets the **Individual-Population** end.

[Fine-brush]

# Molecular Systematics

Detection, description, and explanation of molecular diversity, both within and among species

systematics + evolutionary theory + molecular genetics

Reconstructing evolutionary history based on shared attributes of extant and fossil organisms

# Molecular Systematic Questions

- Geographic Origin(s)
- Species Relatedness
- Species Status
- Classification
- Conservation Priorities
- Evolutionary Novelty

# Systematic Techniques: Molecular

- Nucleotide sequence data - genealogical data!
- Restriction site data - genealogical data
- SNPs - genealogical data (haplotype determination)
- Restriction fragment data - not
- Microsatellite data - not
- AFLP data - not
- RAPDs data - not

Gene genealogy -

# Overview

---

- Molecular Tools: DNA sequences
  - Changes at the DNA level
  - Choosing the best gene(s)
  - Molecular clocks
- Broad brush: Molecular Systematics
  - Interpretation
- Medium Brush: Phylogeography
  - Interpretation
  - Example: crystal darter

# Changes at the DNA level

## Types of Genes

Structural (rDNA)

Protein coding

Non-coding

DNA: C A A C G T

Transcription ↓ ↓

mRNA: G U U G C A

Translation ↓ ↓

Protein: Valine Alanine

Introns

Repetitive DNA

?

# Changes at the DNA level

## Types of Nucleotide Substitutions

---

1	2	3	1	2	3
C	A	A	C	G	T
		C			C
	↓	T		↓	A
		G			G
Valine			Alanine		

- Synonymous (silent)
  - No change in amino acid
  - Most 3<sup>rd</sup> position changes
- Nonsynonymous (replacement)
  - Changes amino acid coded for
  - Most first and all second position changes

# Changes at the DNA level

## Types of Nucleotide Substitutions

---

- **Transitions**
  - Purine ↔ Purine
  - Pyrimidine ↔ Pyrimidine
- **Transversions**
  - Purine ↔ Pyrimidine
  - Pyrimidine ↔ Purine

# Changes at the DNA level

## Modeling DNA Substitutions

---

- Huge amount of sequence data available
- Realistic models of substitutions at different classes of sites
- Models can be incorporated into any of the phylogeny-building methods
- Leads to stronger interpretations of data

# Choosing the best gene(s)

	mtDNA	Nuclear DNA
Inheritance	Maternal	Bi-parental
Ploidy	Haploid	Diploid
Ne	1/4 X	X
Sensitivity		
Broad	*(genome rearrangements)	*** (rDNA-stems)
Medium	** (rDNA)	*(rDNA-loops)
Fine	*** (proteins, D-loop)	** (introns)

# Choosing the best gene(s)

## mitochondrial DNA

---

- Small, compact genome
  - 2 rDNAs
  - 13 protein coding genes
  - 22 tRNAs
  - Gene order "stable"- mostly
  - Most individuals- one sequence
- "Universal primers" (Kocher et al, 1989)
  - Extensive intraspecific polymorphism
  - Sequences available for many taxa
  - Connectivity between studies
  - RFLPs of amplified genes common

# Choosing the best gene(s)

## nuclear introns

---

- Schematic of a typical nuclear protein coding gene

- Primers = exon primed, intron crossing, or EPIC
- Intron sizes can be highly variable among species
  - difficult to predict PCR product size
- Pseudogenes- amplify part of exon also to confirm

# Molecular Clocks

## Generalizations

---

- Can be used to date divergences, but remember:
- Usually rely on biogeographic or fossil data
- Not like timepiece- “stochastically constant”
  - Most ‘accurate’ averaged over long time periods
- Can have different rates for:
  - Different lineages
  - Different genes
  - Different categories of sites along a gene
- Better than nothing!?!

# Molecular Systematics (Phylogenetics)

---

- Attempt to reconstruct *historical relationships* among organisms
  - Use of state-of-the-art methods to look into the past
- Draws from:
  - Molecular genetics (tools)
  - Molecular evolution (how tools work)
  - Statistical hypothesis testing (how to address questions)
- *Most common uses -*
  - Resolving taxonomic uncertainties
  - Defining management units

# Traditional vs. Molecular Systematics

---

- Traditional

- Direct observation of shared attributes
  - morphology (fossils too)
  - physiology
  - development

- Molecules

- Shared attributes = mostly DNA sequence data
  - Approach can be used even when morphological differences few or misleading
  - Number of characters to compare virtually unlimited!

# Conclusions

## Subfamily Anodontinae phylogeny

---

- *Alasmidonta*
  - (*A. heterodon*)(*A. undulata*/ *marginata*/ *varicosa*)
  - *A. viridis* ???
- *Lasmigona*: subgenera recovered
- COI = good tool for species level ID
- Inclusion of many genera = chaos!
  - Not enough signal in data
  - "Prodigious Polyphyly" ???

# Phylogeography

(Avice 1987)

---

- Comparison of *phylogenies* of populations or species with their geographic distributions, OR spatial analysis of gene lineages
- Draws from:
  - phylogenetics
  - population genetics
  - biogeography } "bridges gap"
- Most common uses -
  - delineate distinct population segments (population subdivision)
  - PRESENT DAY forces- gene flow/effective population sizes
  - HISTORICAL EVENTS- habitat fragmentation and expansion

# Phylogeography

Methods- detecting population structure

---

- Geneological-based
  - Phylogenetic analysis
  - Haplotype networks
  - Nested clade analysis
- Frequency-based
  - F-statistics
  - AMOVA

# Phylogeography

## The Coalescent

“model of lineage sorting and genetic drift run backwards in time to common ancestor” (Harding 1996)

- Pathways connecting mothers and daughters
  - Trace back to 1 female
- Variance among females in contribution of daughters
  - Gene tree grows and self-prunes
- Demographic factors that influence family size important
  - Chances of lineage survival decrease with population size

# Phylogeography

## Demography - Phylogeny connections

---

### Phylogenetic categories of relationships (Avice 1983)

- Monophyly- barrier concordant with earlier subdivision
  - female lines trace back to single ancestor
- Monophyly- barrier concordant with earlier subdivision
  - female lines trace back to single ancestor
- Polyphyly- barrier discordant with earlier subdivision
  - Regions share a lineage
- Paraphyly- barrier at periphery of range
  - No unique lineage

# "Tree Thinking"

## Gene Trees vs. Species Trees

---

Gene trees can differ from one another and from the species tree

# Phylogeography

Geneological Concordance (Avice 1996, 2000)

---

- **ESUs:**
  - I. Concordance among sequence characters within a gene
  - II. Concordance in major partitions using multiple genes
- **Areas of conservation relevance:**
  - III. Concordance in geography of gene-tree partitions across multiple species
  - IV. Concordance in gene-tree partitions by geographic provinces

# Gene Trees vs. Species Trees

**Gene Trees vs. Species Trees** Read the figure from the bottom to the top. The oval at the bottom represents an ancestral species containing six alleles for a gene. The alleles are related to each other as shown by the gene phylogeny inside the oval: Each allele was derived from its ancestors via a series of mutations. Moving up the figure, a speciation event produces two sister species from the ancestral species. By selection of drift, one species loses alleles 3, 5, and 6, while the other species loses alleles 1, 2, and 4. Moving up the figure, another speciation event occurs, followed by the loss of alleles in its descendant species. We now have: species A, containing alleles 1, 2, and 4; species B, containing allele 3; and species C, containing alleles 5 and 6. Now imagine that we sequence a single allele from each species (boxes) and reconstruct a phylogeny. In the true species tree, species B and C are closest relatives. The gene tree and the species tree show different branching patterns. Note that if we had sampled more extensively from each species and found all six alleles, we would have realized that the gene tree was a misleading guide for estimating the species phylogeny, because the alleles from species A, for example, would not cluster together. After Ruvolo (1994).

# Species Concepts and Criteria

# Population Genetics and Molecular Systematics

- Different biological disciplines
- Genetic data have enabled an interface of sorts between the two—which is good, but potentially dangerous when the parameters of the study in question are not explicit
- Genetic data are not magic

# Population Genetics and Molecular Systematics

- While the techniques of genetics have opened doors (or windows) between fields, at times fundamental concepts have had to be recast; the wheel has been reinvented (in my opinion unnecessarily) on a number of occasions
- Nevertheless these debates have enabled a clearer understanding of the complementarity of systematics and population genetics; it's not as though one were superior: each is best equipped to deal with certain kinds of questions

# Population Genetics, Molecular Systematics, and Species

- “The species problem” has not, nor will it ever go away
- Species concepts have been viewed as a nexus for synthesizing biology and as distraction from and obstacle to scientific progress
- Regardless, understanding the perspective of any given study towards species and speciation is critical to interpretation

Is it important? Yes.

- Is it ok that people disagree?  
Absolutely.

# General Background

- Various, often conflicting approaches to “the” species problem, confounded by the conflation of different kinds of genetic data

# General Background

- Various, often conflicting approaches to “the” species problem , confounded by the conflation of different kinds of genetic data
- Literature devoted to the species problem has not abated

# General Background

- Various, often conflicting approaches to “the” species problem , confounded by the conflation of different kinds of genetic data
- Literature devoted to the species problem has not abated
- Legislation has not kept up with current debates and issues (as if any of us could)

# Words, words, words

- Arguments over definitions lead nowhere...by definition...

# Species, speciation, units, and continua

- Woodger's dilemma: Species boundaries and the biological species concept

# Species, speciation, units, and continua

- Woodger's dilemma: Species boundaries and the biological species concept
- Species concepts and criteria: What are they supposed to do?

# Species, speciation, units, and continua

- Woodger's dilemma: Species boundaries and the biological species concept
- Species concepts and criteria: What are they supposed to do?
- Do we need to regard species as biologically equivalent in terms of their origin and/or maintenance?

# Species, speciation, units, and continua

## Limits of the biological species concept

- Confined to extant biparental sexually reproducing organisms
- Admits a continuum in which the partitions may not reflect history
- Reproductive isolation (as "speciation") may occur late in the "ontogeny" of species concepts

# Species concepts and criteria

- “Biological”
- Cohesion
- Phylogenetic
  - I
  - II
  - III...

ALFRIED P. VOGLER  
ROB DESALLE

American Museum of Natural History  
Central Park West at 79th Street  
New York, NY 10024, U.S.A.

Figure 1. Average minimum (left in each panel) and average maximum (right in each panel) sequence divergence in mtDNA at various hierarchical taxonomic levels. The level of sequence divergence was taken from the literature from restriction fragment length polymorphism (RFLP) or from DNA sequencing (SEQ) studies. The data were split into three taxonomic levels as designated by the authors of the various publications: within populations (INTRA), between populations (INTER), and between "closely related species" (SPECIES). Variances of the mean minimum and maximum sequence divergence are indicated by bars. Both variances are given in the figure. The data were taken from a selection of papers published before the middle of 1991 (see Appendix). The total number of studies included in each of the comparisons is given at the top of each panel. The full data set used in this figure is available from the authors upon request.

# Tree-based conceptions versus Character-based Criteria

# Example: crystal darter

## *Crystallaria asprella*

---

- Once widely distributed in Eastern US
- Severe population decline- habitat degradation
- Exists in isolated populations
  - 6 Southern states: MS and Gulf drainages
  - Recently discovered Elk River, WV
- Assess degree of connectivity between populations

(Morrison, Lemarie, Wood, and King, in press)

# Example: crystal darter

*Crystallaria asprella*

---

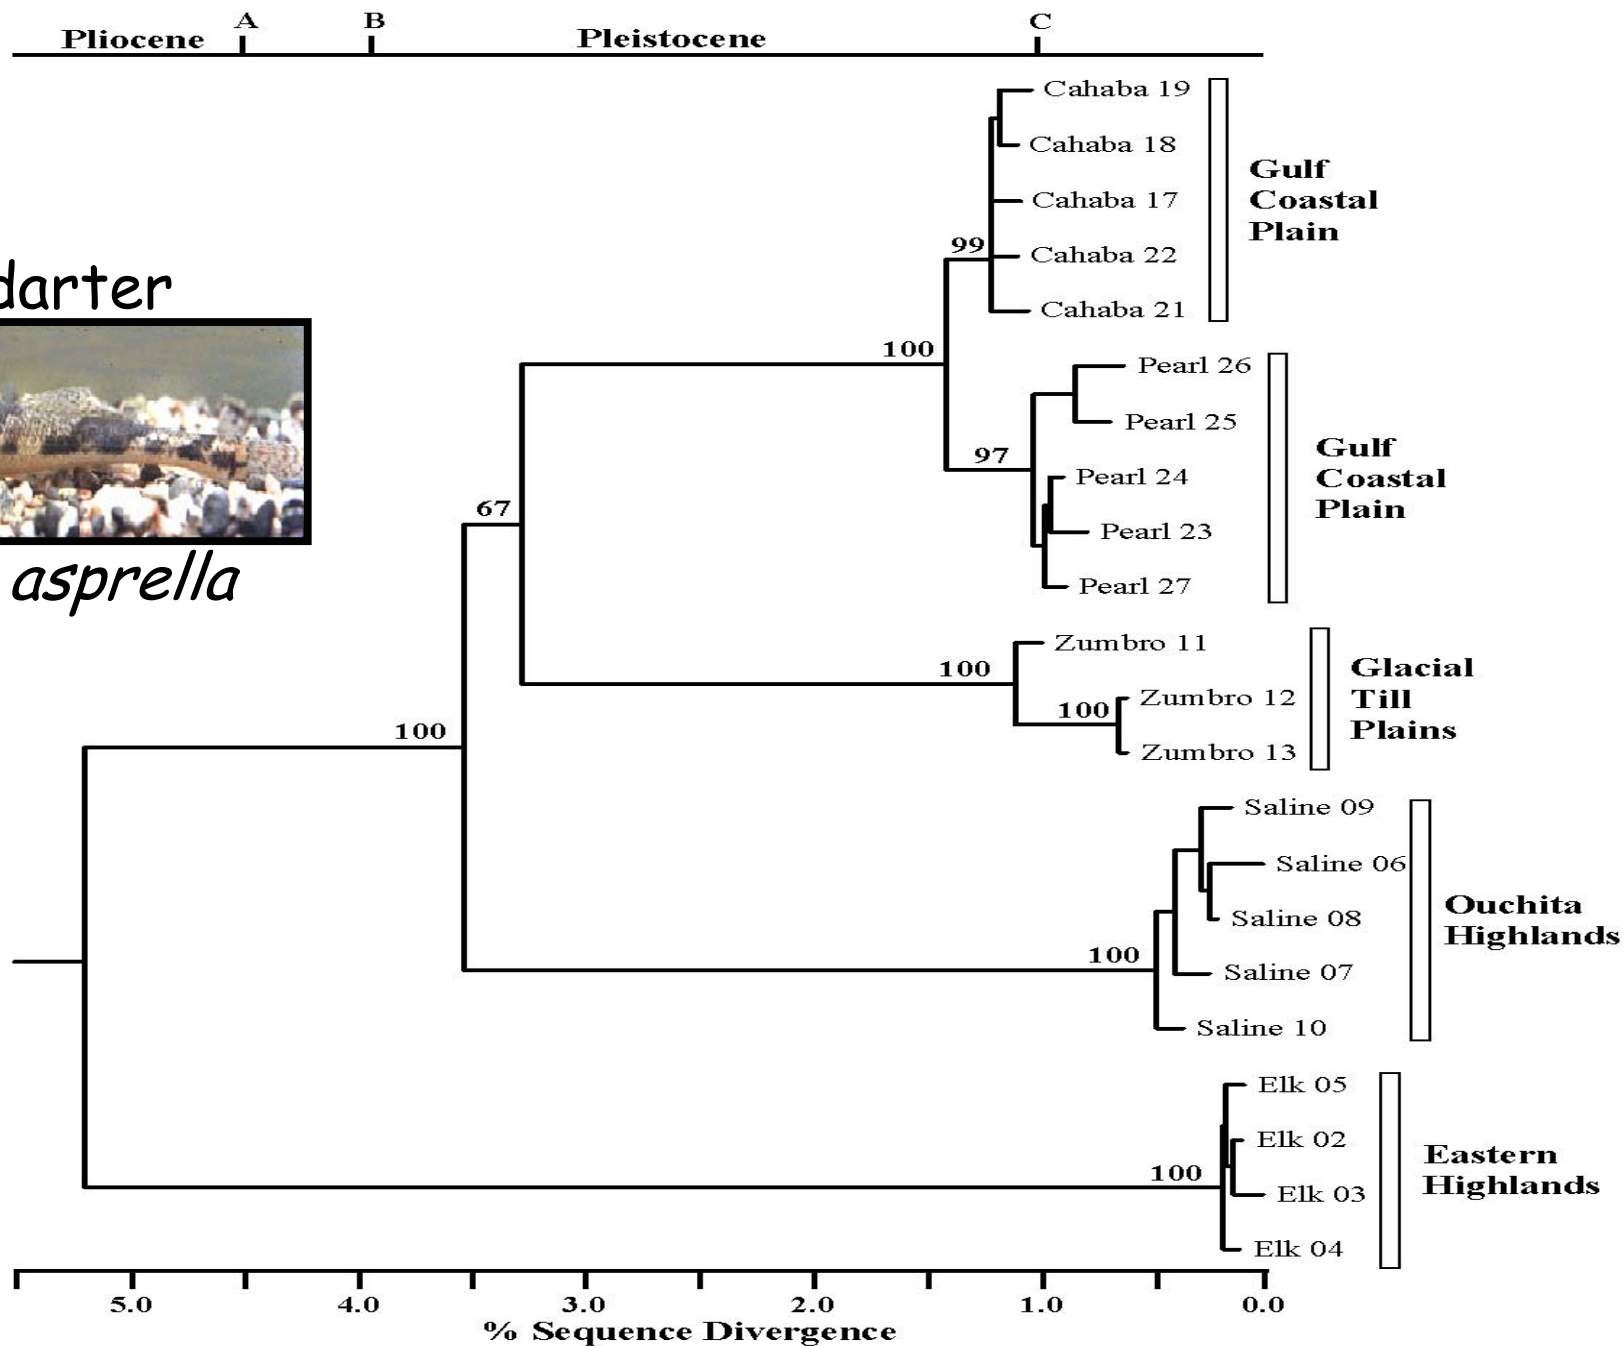

Zumbro River, MN

Saline River, AR

Elk River, WV

Pearl River, MS  
Cahaba River, AL

# Accurate Taxonomy in Conservation Biology

Does it really matter?

---

- May not be recognizing extent or limits of diversity
  - Genetically distinct (cryptic) species unrecognized?
  - Legal protection for abundant species?
  - Overlooking sources of genetic diversity to help impoverished populations
- Confusion caused by hybrids
- Forensics- identifying poached species

# Trees as Networks

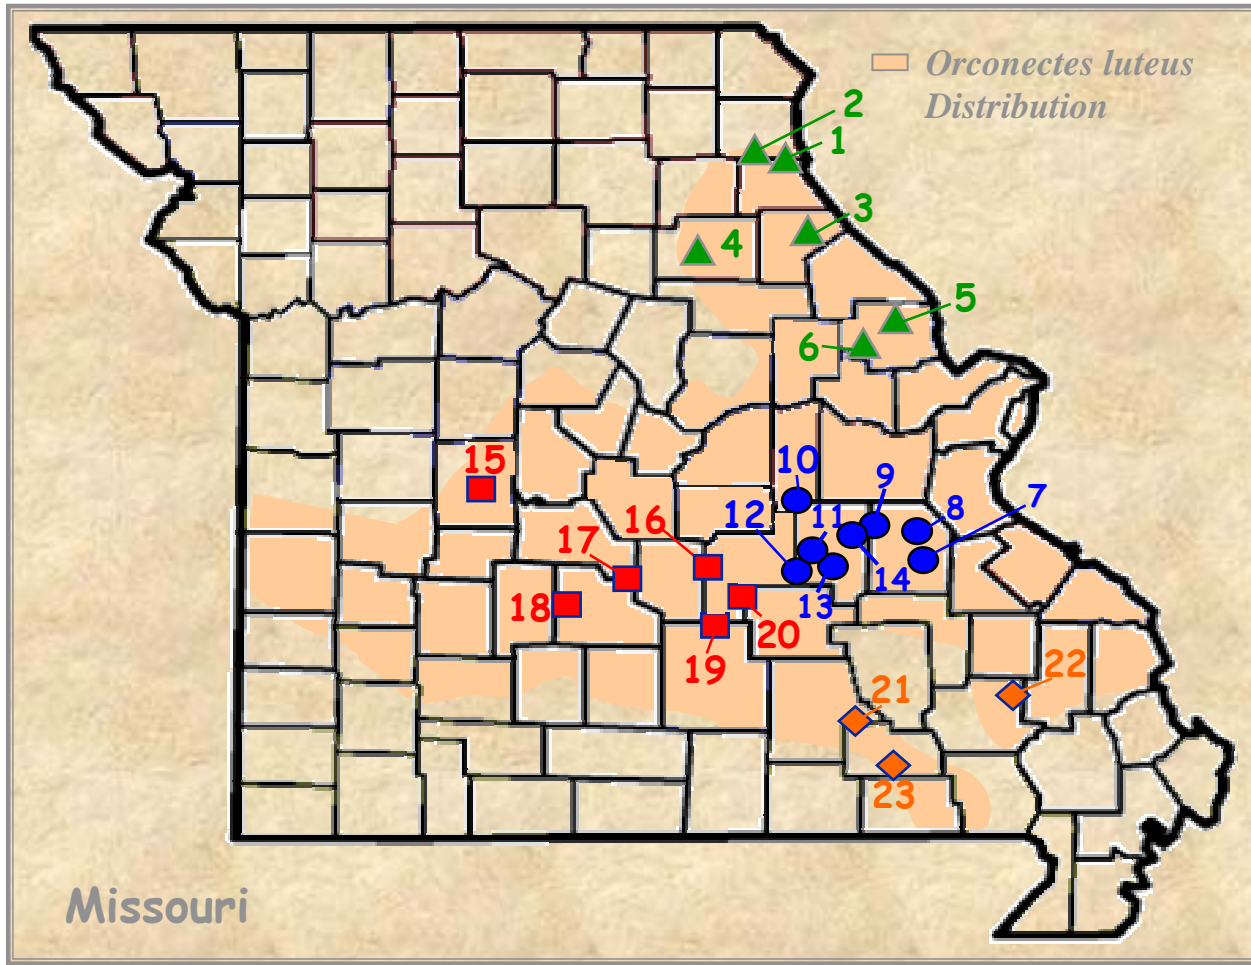

- The interface of Systematics and Population Genetics
- Network incorporates reality of population genetics
  - Reticulate relationships
  - Hybridization
  - Back mutation
  - Recombination

# Conclusions

---

 High estimate of  $F_{ST}$  from 16s Data ( $F_{ST}=0.937$ )  
High level of Population Structuring

 Nested Analysis Indicates:  
Past fragmentation involved with higher-level (older) clades.  
Restricted gene-flow (Isolation By Distance) between Big River and Merimac River Populations.  
Contiguous Range Expansion for Current River, Little Piney, and Big Piney Populations.

 Three Distinct ESUs lacking historical and recent genetic and ecological (color morph & geography) exchangeability - distinct species! (with further genetic subdivision within these groups)

# Optimality Criteria

- Maximum Parsimony (minimize character change over a tree - tree length)
- Maximum Likelihood (maximize the likelihood)
- Minimum Evolution (obtain all trees within a certain genetic distance)
- NOT neighbor-joining, etc. - algorithms

# Models for all!

- MP - Model is implicit (1:1) or explicit (weighting matrix)
- ML - Model is explicit
- ME - Model is explicit
- How do you choose a model?

# Hypothesis Testing Hierarchy

(Huelsenbeck & Crandall 1997)

# Alasmidonta

## COI MP Tree

# Now you have a tree - what's next?

- Confidence in a tree - bootstrap
- Hypothesis testing with a tree (likelihood approaches)
- Testing for correlations with phylogenetic diversity

# Aims of systematics

- To describe and arrange our observations and understanding of life on Earth in an empirical, efficient, and recoverable manner

# Aims of systematics

- To describe and arrange our observations and understanding of life on Earth in an empirical, efficient, and recoverable manner
- To provide an information retrieval system proscribed in such a way that alterations and new discoveries can be accommodated and tracked through one or more scientific codes (e.g. ICZN)

# Aims of systematics

- To enable the furtherance of all biological understanding, ecological, behavioral, biogeographic, and otherwise, through an information system that facilitates empirical testing and analysis of evolutionary history. That is, by constructing a lens through which evolution itself may be explored

Systematics does not equal taxonomy

Taxonomy does not equal nomenclature

- Taxonomy is an arm of systematics devoted to description, nomenclature, and classification

# History

- Early debates surrounded “schools” of systematics: Evolutionary taxonomists, “numerical taxonomists” (who embraced phenetic methods), and phylogenetic systematists (cladists)

# Phylogenetic Systematics (Hennig, 1966)

- Incorporates taxonomy
- Involves quantification, character analysis, and hypothesis testing

# Why phylogenetics?

- Enables the elucidation of natural (=monophyletic) groups and natural classification

# Why phylogenetics?

- Enables the elucidation of natural groups and natural classification
- Enables the most efficient possible information retrieval system

# "Reptilia"

# Why phylogenetics?

- Enables the elucidation of natural groups and natural classification
- Enables the efficient possible information retrieval system
- Enables inference of the sequence and number of evolutionary events and the testing of historical evolutionary hypotheses

# So what?

- Enables the testing of historical hypothesis
  - Adaptational hypotheses
  - Biogeographic hypotheses
  - Behavioral hypotheses

# Why phylogenetics?

- Enables the elucidation of natural groups and natural classification
- Enables the efficient possible information retrieval system
- Enables inference of the sequence and number of evolutionary events and the testing of historical evolutionary hypotheses
- Enables understanding and prioritization of conservation priorities

# Alternative classifications

- “Evolutionary” taxonomists would accept a demonstrably paraphyletic group (e.g. Reptilia)
- “Cladists” accept only monophyletic groups in classification

# History

- Early debates surrounded “schools” of systematics: Evolutionary taxonomists, “numerical taxonomists” (who embraced phenetic methods), and phylogenetic systematists (cladists)
- Primary contributions of phylogenetic systematics: Monophyly and polarity (apomorphy). More broadly: An efficient information retrieval system with the potential to reflect evolutionary history in classification

# Key Concepts

- Monophyly:  
Tree-based term
- Polarity (apomorphy):  
Character-based term

# Monophyletic Group

- A group that includes a common ancestor and all of its descendants
- A group with unique and unreversed group membership characters

# Monophyly and polarity

# Paraphyletic Group

- A group that includes a common ancestor and some but not all of its descendants
- A group with unique but reversed group membership characters

# Paraphyletic Group: "Reptilia"

# Polyphyletic Group

- A group in which the most recent common ancestor is assigned to some other group
- A group whose membership characteristics are not uniquely derived

# Polyphyletic Group: Haemothermia

# Polarity-related terms

- Apomorphy: Derived character
  - Synapomorphy: Shared derived character
  - Autapomorphy: Uniquely derived character (no information) [example - tetrapod limbs]

# Polarity-related terms

- Apomorphy: Derived character
  - Synapomorphy: Shared derived character
  - Autapomorphy: Uniquely derived character (no information)
- Plesiomorphy: "Primitive" character
  - Symplesiomorphy: Shared primitive character  
[example - lizard limbs]

# Polarity-related terms

- Apomorphy: Derived character
  - Synapomorphy: Shared derived character
  - Autapomorphy: Uniquely derived character (no information) [example - tetrapod limbs]
- Plesiomorphy: "Primitive" character
  - Symplesiomorphy: Shared primitive character  
[example - lizard legs]
- Homoplasy: Parallelism, reversal, convergence [example - vision]

A cladogram depicts relative recency of common ancestry.

No more

No less

A cladogram depicts relative recency of common ancestry.

Assumption 1:

Assumption 2:

Descent with modification

Cladogenesis

# History

- Ultimately, as most agree that phylogenetics are important and interesting, the debates have shifted to phylogenetic inference methods

# History

- Ultimately, as most agree that phylogenetics are important and interesting, the debates have shifted to phylogenetic inference methods
- To a certain degree, these debates have proceeded at cross purposes

The best one can hope to do is be aware of the issues, understand the methods in order to evaluate critically a given data set's relevance to a conservation question

# Phylogenetic Inference/Reconstruction Methods

- How do you go from this...

## Characters

## Taxa

A	0	0	0	0	0	1

E	0	1	1	1	1	1

# Phenetic Techniques

- Clustering methods based on overall similarity

# Phenetic Analyses

- WPGMA

	perch	coelocanth	salamander	frog	turtle	human	gecko	snake	alligator	budgy
perch		85	62	62	69	54	54	62	54	23
coelocanth			77	77	85	69	69	77	69	38
salamander				100	77	77	54	46	62	46
frog					77	77	54	46	62	46
turtle						85	85	76	85	54
human							69	62	69	69
gecko								92	85	54
snake									76	46
alligator										69
budgy										

# WPGMA

The similarity between perch and (salamander, frog) is  
 $(\text{perch:salamander} + \text{perch:frog} + \text{salamander:frog})/3$ , or  
 $= (62 + 62 + 100)/3$   
 $= 75$

and then, too, the similarity between (salamander, frog) and gecko is  
then

$(\text{salamander:gecko} + \text{frog:gecko} + \text{salamander:frog})/3$   
 $= (54 + 54 + 100)/3$   
 $= 69$

# Phenetic Techniques

- DNA-DNA hybridization

# Distance Analyses

- Neighbor-joining

# Issues with Phenetics

- Metricity, negative branch lengths, triangle inequality

# Optimality Criteria

# Phylogenetic Inference/Reconstruction Methods

- Parsimony: Justified in part by Hennig's so-called Auxiliary Principal, namely that we not hypothesize homoplasies (convergences, parallelisms, reversals) beyond what are required by the data.

The idea derives from Occam's Razor, ie that the explanation requiring the fewest assumptions (in this case the **shortest tree**) is the most robust, the best corroborated, etc.

# Phylogenetic Inference/Reconstruction Methods

- Parsimony: Justified in part by Hennig's Auxiliary Principal, namely that we not hypothesize homoplasies (convergences, parallelisms, reversals) beyond what are required by the data.
  - Most generalizable; accommodates any kind of phylogenetic data (morphological, molecular, behavioral, etc.) with equal aplomb

# Parsimony and character support

Parsimony

Neighbor Joining  USGS  
Science for a changing world

# Rooting

- The primary result of a phylogenetic analysis is a network that does not in and of itself imply exclusive relationship because it does not make polarity statements a priory
- This requires rooting the tree through the explicit inclusion of a suitable outgroup

# Branch Support

- Straightforward character mapping
- Bootstrap values
- Bremer values

# Dealing with data, results

- The most parsimonious tree is the tree that requires the fewest steps. Multiple equally short trees may obtain. This reflects indecisive data.

# Dealing with data, results

- The most parsimonious tree is the tree that requires the fewest steps. Multiple equally short trees may obtain. This reflects indecisive data.
- Interpreting lack of resolution

# Morphology and Molecules

- Qualitatively different

# Morphology and Molecules

- Qualitatively different
- Quantitatively the same?

# Patterns of Substitution

- Silent versus replacement substitutions
- 1<sup>st</sup>, 2<sup>nd</sup>, and 3<sup>rd</sup> positions
- Transitions (purine >>>purine or pyrimidine>>>pyrimidine) and transversions (purine<<<>>>pyrimidine)

# Phylogenetic Inference/Reconstruction Methods

- Parsimony: Justified in part by Hennig's so-called Auxiliary Principal, namely that we not hypothesize homoplasies (convergences, parallelisms, reversals) beyond what are required by the data
- Maximum Likelihood: Model-based method deriving in part from justification that parsimony may not always perform with statistical consistency (the long branch attraction epiphenomenon)

# ML Seeks to Incorporate

- Recognized molecular evolutionary principles
- Frequencies of change and rates of evolution implied by those principles

So as to “weight” characters according to their inferred importance

# Models

- Parameterization
- Complication

# Phylogenetic Inference/Reconstruction Methods

- Bayesian Analysis:  
The Monte Hall Problem (credited to W. Wheeler) and the use of prior probabilities
- Asserted to be generalizable to all forms of data with similar model-able features as strict maximum likelihood

# Debates

- Probabilism versus parsimony

# Molecular "versus" Morphological Data

- Historical and current debate with strong advocates on both sides

# Molecular "versus" Morphological Data

## Molecular proponents:

- Morphology is subject to convergence, has contributed nothing to systematics or is otherwise irrelevant (Graur, Hedges)
- Molecular data constitute an "independent" test (!)
- Concerns over data "swamping"

# Molecular "versus" Morphological Data

## Morphological proponents:

- Molecular data do not feed the process of systematics adequately (e.g. with reference to character circumscription or, commonly, type species)
- Commonly practiced molecular analyses do not enable an understanding an understanding of synapomorphy or character support

# Morphology “versus” molecules redux

- Molecular data are not superior to morphological data

# Morphology “versus” molecules redux

- Molecular data are not superior to morphological data
- Morphological data are not superior to molecular data

# Morphology “versus” molecules redux

- Molecular data are not superior to morphological data
- Morphological data are not superior to molecular data
- No class of data is inherently superior to any other class of data; rather they complement one another if analyzed properly.

# Morphology “versus” molecules redux

- Molecular data are not superior to morphological data
- Morphological data are not superior to molecular data
- No class of data is inherently superior to any other class of data; rather they complement one another if analyzed properly.
- Molecular data provide a fantastically rich source of phylogenetic information

# Morphology "versus" molecules redux

- Molecular data are not superior to morphological data
- Morphological data are not superior to molecular data
- No class of data is inherently superior to any other class of data; rather they complement one another if analyzed properly.
- Molecular data provide a fantastically rich source of phylogenetic information
- Morphological (and behavioral and ecological) data represent the foundation on which the basic description of the natural world rests

# Combinability: Options

- Simultaneous analysis of all data sets

# Combinability: Options

- Simultaneous analysis of all data sets
- A priori partitioning of data sets followed by separate analyses and post hoc decisions as to how to deal with discrepancies

# Combinability: Options

- Simultaneous analysis of all data sets
- A priori partitioning of data sets followed by separate analyses and post hoc decisions as to how to deal with discrepancies
- Testing for heterogeneity or incongruity

- A chainsaw, like any good tool can be applied towards many useful purposes
- Likewise genetic data may be used to answer a variety of questions that require different strategies of hypothesis testing, data gathering, and analysis
- Genetics is a meaningless term in and of itself unless contextualized

# Background

- "Genetics" used variously in conservation
- Distinction between population viability-related concerns and inferring historical relationships among management units

# Salient Points

- Methodological issues in phylogenetic analysis and delineation of conservation “units”
- Correspondence (or lack thereof) of delineated management units and taxonomic epithets
- In the context of delineating units (intra-specific and otherwise), genetic data offer a promising set of characters, but they are not the only characters, or necessarily the most relevant

- A chainsaw can also be applied irresponsibly

## Genetic evaluation of a proposed introduction: the case of the greater prairie chicken and the extinct heath hen

"Tom Chase hasn't given up..."

Dunlop, 2004: 51

# Punchlines

- The notion of subspecies can lend itself to misinterpretation (Zink, 2004) in a phylogenetic framework
- Molecular, morphological, ecological, and behavioral data often corroborate one another

# Phylogeography

- The application of phylogenetic graph theory to population-level biogeographic questions through the medium of mitochondrial DNA

# Phylogeography

- The uniparental inheritance of mitochondrial DNA means that the relationships among mitochondria are hierarchical, much like the relationships among species and taxonomic groups

# Phylogeography

- This enables the same kinds of powers cladograms offer the study of species to the study of populations, the idea being that recent evolutionary history can be represented as a nested hierarchy rather than a reticulate network of individual relationships

# Phylogeography

- And so the question becomes whether the relationships among mitochondria necessarily reflect the relationships among populations, species, or even individuals

# Caveats to character-based methods

- Over-diagnosis or under-diagnosis as a result of poor sampling of individuals or genes

# Caveats to character-based methods

- Over-diagnosis or under-diagnosis as a result of poor sampling of individuals or genes
- Although these examples are highly simplified, multiple characters with congruent distributions (fixation patterns) are desirable. No one would name a new species on the basis of a single nucleotide polymorphism

# Caveats to character-based methods

- Over-diagnosis or under-diagnosis as a result of poor sampling of individuals or genes
- Although these examples are highly simplified, multiple characters with congruent distributions (fixation patterns) are desirable. No one would name a new species on the basis of a single nucleotide polymorphism
- Identification of the species boundary?

# Caveats to character-based methods

- Over-diagnosis or under-diagnosis as a result of poor sampling of individuals or genes
- Although these examples are highly simplified, multiple characters with congruent distributions (fixation patterns) are desirable. No one would name a new species on the basis of a single nucleotide polymorphism
- Identification of the species boundary?
- Proliferation of names?

# Implications of a character-based approach

- Solution to Woodger's dilemma (= "speciation" is instantaneous, corresponding to fixation)
- A single individual suffices to refute the hypothesis of character fixation
- Generalizable (all organisms have characters)
- Focus is on utility, i.e. on reconstructing the past, not future stability of lineages or species names
- Allows for the study of reproductive isolation without hanging up taxonomy & systematics

# The role of subspecies in obscuring avian biological diversity and misleading conservation policy

Robert M. Zink

*Bell Museum, 100 Ecology Building, University of Minnesota, St Paul, MN 55108, USA (rzink@biosci.cbs.umn.edu)*

Subspecies are often used in ways that require their evolutionary independence, for example as proxies for units of conservation. Mitochondrial DNA sequence data reveal that 97% of continentally distributed avian subspecies lack the population genetic structure indicative of a distinct evolutionary unit. Subspecies considered threatened or endangered, some of which have been targets of expensive restoration efforts, also generally lack genetic distinctiveness. Although sequence data show that species include 1.9 historically significant units on average, these units are not reflected by current subspecies nomenclature. Yet, it is these unnamed units and not named subspecies that should play a major role in guiding conservation efforts and in identifying biological diversity. Thus, a massive reorganization of classifications is required so that the lowest ranks, be they species or subspecies, reflect evolutionary diversity. Until such reorganization is accomplished, the subspecies rank will continue to hinder progress in taxonomy, evolutionary studies and especially conservation.
